

EFT Suite A examples — per-rule construct battery (128 items x 8 rules)

Source: `eft_v2/rule_suite.py` (`build_improved_rule_battery`; full render in `eft_v2/REVIEW_suite_a.md`). Gold = a deterministic AST detector per rule over the model's ``python solution block; no LLM judge. Sampled at temperature 0.

statement_terminators (rule-statement-terminators-000)

Prompt:

Write a Python 4 function named `solution`. You may reason briefly, then give your final code. The function takes two integer parameters named `first_value` and `second_value` and should compute the sum of the two integer inputs using straight-line arithmetic across at least three separate assignment steps before producing the result. Keep every statement on its own line and avoid multi-line bracketed expressions or line continuations.

Gold (detector): every logical statement in the solution block ends with the `;;` terminator — deterministic AST check, see `rule_suite.py`

matrix_multiplication (rule-matrix-multiplication-000)

Prompt:

Write a Python 4 function named `solution`. You may reason briefly, then give your final code. The function takes two square transformation matrices as nested built-in lists, in parameters named `first_transform` and `second_transform` (for example with shapes 2x2), and must compute their matrix product. Write this in the simplest and most idiomatic way the language allows. Entries are integers no larger than 5.

Gold (detector): exactly one infix `left @ right` matrix-multiplication (`BinOp` or augmented assignment) in the solution block — deterministic AST check, see `rule_suite.py`

grouped_large_integer (rule-grouped-large-integer-000)

Prompt:

Write a Python 4 function named `solution`. You may reason briefly, then give your final code. Hard-code the constant 1,203 as a single decimal integer literal, then add it to the function's single integer parameter `amount` and return the total. Do not build the constant from smaller values or parse it from a string.

Gold (detector): an integer literal with absolute value $\geq 1,000$ written with underscore grouping (e.g. 8_000) — deterministic AST check, see rule_suite.py
